Letter from the Commissioner

May 2019

Dear Parkies and Plant Lovers:

In 2018 the New York City Park's system grew to 30,000 acres of parkland. This is a testament to the growing call for green space from the over 8.5 million residents of New York City and the important role that parks play. Our metropolis relies on these parklands to provide sanctuary for its residents, clean the air and water, keep temperatures cool, mitigate flooding and storm surges, and be the anchor for its rich biodiversity.

The health of our parklands, particularly our nearly 10,000 acres of natural areas, depends on the biodiversity of these ecosystems. In recognition of the critical role that native plants play in keeping our ecosystems diverse and providing healthy habitat, the City Council passed Local Law 11 in 2013. This law is aimed at decreasing the presence of exotic monocultures in favor of native plants throughout the landscapes of New York City, big and small.

In compliance with Local Law 11, which requires the use of native species when planting in a natural area and the creation of a native plant guide updated every 5 years, I present the 3rd Edition of the Native Species Planting Guide. With over 1,300 native plant species local to the area, there are plenty of species to choose from when designing for natural green spaces. Many of the species listed in this guide are available from the Greenbelt Native Plant Center, which has been growing native plants for use in ecological restoration projects for over two decades. This guide lists all of the native plants of New York City–if you are planting in a natural area as defined by this guide, you must use the plants catalogued here. If you are planting outside these areas, please do your best to incorporate natives into your sustainable designs. No matter where you are planting, you should never use invasive species, a list of which is also provided in this guide.

This guide is in keeping with NYC Nature Goals 2050, which was highlighted in OneNYC. Nature Goals 2050 was the result of a coalition of more than 75 organizations from different sectors, which came together over five years to develop shared goals and targets for urban nature in New York City. A key element of Nature Goals is support for biodiversity and habitat, with one of the identified targets being to sustain populations of all known native species that existed in the city in 2015. By using the species listed here in all plantings, big and small, we can together reach the goals set forth in Local Law 11, Nature Goals 2050, and OneNYC and increase the native biodiversity of our lush metropolis.

Happy planting!

Sincerely,

Mitchell J. Silver, FAICP, Hon. ASLA

Mendel

Commissioner

The Value of Native Plants

New York City has over 30,000 acres of parkland, over a third of which is considered natural. The natural areas of New York City serve as anchors of biodiversity for the region. Corridors of habitat within the built environment facilitate movement of pollinators, small mammals, and birds between these larger natural areas and the broader region. Native plants in landscaped parks of all sizes, in addition to those in natural areas, are the primary resources needed to sustain our city's resident and migratory wildlife. Both natural areas and designed landscapes consist of a variety of planted and natural habitats ranging from small rain gardens to large coastal grasslands.

According to the first annual <u>State of New York City's Plants</u> published by the New York Botanical Garden in 2018, there are 1,359 plant species native to the five boroughs. Many native plant species persist in protected natural areas, which also help provide clean air and water as well as recreational, mental health, and well-being benefits for the nearly nine million people inhabiting New York City. However, as the natural world continues to be encroached upon and the climate continues to shift, this flora is increasingly at risk of being lost or diminished. One way to combat this risk is to wisely choose native plant species for planting plans, to ensure the lasting legacy of our native flora persists.

Using native plants is a way to support the ecosystems of New York City. Local Law 11 of 2013 was enacted to increase biodiversity within these ecosystems using native plants (§ 18-141 NYC Admin. Code). Every planting choice we make is a valuable opportunity to make a lasting, positive effect on the landscape. Because plants are a critical building block of ecosystems, designing with species not native to our area risks reducing the value of habitat and forage resources for various species that depend on these plants for their existence. The native plant species in this guide have evolved with our local wildlife to provide the right source of food and shelter at the right time of year.

Introducing native plant species in a highly designed space can also transform the way the public looks at these species. Designers and conservationists have the opportunity to springboard native species onto the public stage when they showcase native species in parks, greenstreets, and other community spaces. Currently, there are a few native species that are commonly used in design and restoration representing only a fraction of our city's flora. This guide highlights the potential for expanding this narrow palette if designers, gardeners, and landscape architects are willing to work with new species that are not common in the current market.

The Greenbelt Native Plant Center (GNPC), the municipal native plant nursery operated by NYC Parks, embraces a conservation approach and has extensive knowledge of all the species listed in this guide. GNPC staff can assist in species selection for projects and are confident that there is a native plant that can be successful in any scenario. Through their field and greenhouse experience, staff at GNPC have an intimate knowledge of soil, light, and water requirements necessary for plant survival, as well as what propagation methods are successful for over half of New York City's native flora. Their expertise is invaluable when choosing the right plant for the right place.

This guide aims to be an inspiration to harness the power of native species in the urban landscape for a broad range of ecosystem services, including stormwater management and coastal resiliency. For further information on the value of native plant species, please see the original introduction to this guide <u>published in 2014</u>.

How to Use This Guide

This guide is a resource written to provide support for increasing biodiversity in our urban ecosystems. The information in this guide should not be the sole resource for planting decisions, rather it should be used in conjunction with a complex analysis and inventory of soils, hydrological conditions, light resources, and the existing native plant communities on or near a site. It is meant to support the creative, innovative, careful, and conscious choices made by New York City's landscape architects, horticulturists, ecologists, foresters, and other professionals. The New York City Native Species Planting Guide is updated every five years to reflect new information on species' use as well as nomenclature. The sections of this guide have been highlighted and described below.

Ecosystems of New York City

The New York Natural Heritage Program (NYNHP) has classified the ecosystems for New York City. This section, adapted from the plant communities in the NYNHP classification system, highlights the characteristic species that are common throughout the NYC ecosystems. These lists can be referenced when designing the landscape to mirror natural habitat composition.

Planting Near Natural Areas

Planting native plants near or adjacent to undeveloped spaces, including NY State Parks, DEC Bluebelts, Unique Areas, and NYC Parks' Forever Wild or other natural areas can help buffer critical habitat from invasive plants that may otherwise colonize disturbed edges. This section includes plant lists of appropriate species that complement the naturally occurring native species found in a particular natural area type.

Forever Wild is NYC Parks land conservation and protection program focused on natural areas. Only native plant species can be planted in these areas, and preference should be given to native species plant selection when planting adjacent or in proximity to these sites. Maps have been provided for each borough to show areas within New York City designated as Forever Wild.

Invasive Species in New York and Native Alternatives

Invasive species are prevalent throughout New York City and some of these plant species are now regulated and/or prohibited for use or sale within the state of New York. These lists, as well as native alternatives can be found in this section. In addition, we have created a list of "problematic species" that are not regulated by the State but are either regulated in neighboring states or have been flagged as expanding into natural areas.

Stormwater Tolerant Species

Green infrastructure practices, such as right-of-way (ROW) rain gardens, stormwater greenstreets and Parkland retrofits, are being installed throughout the city to capture stormwater at its source and before it contributes to pollution within the city's waterbodies. New York City provides bountiful opportunities for innovative green infrastructure designs; highlighted in this guide are native species that are well suited to an array of such projects.

Species Least Preferred by Deer

Staten Island and the Bronx are home to an increasing number of deer. Planting in areas where deer populations are large presents a number of challenges. Native plant species that are least preferred by deer are provided in this section; however we must stress that no plant species is deer resistant.

Planting in the Built Landscape

Highly altered landscapes can be some of the most difficult areas to create sustainable designs. A successful way to limit the number of invasive species that may exist in these areas is to cover the ground with appropriate native species. This section provides suggestions of natural habitats to mirror and species that can thrive in closed canopies, tree beds, invaded wetlands and more.

Native Plant Descriptions

This section contains descriptions of over 400 common native plant species. Research and field experience helped to provide detailed information on ecosystem requirements and design values for each species.

Ecosystems of New York City

The mid-Atlantic region boasts a rich and diverse indigenous flora. The ecosystems of New York City are comprised of various native plant communities. Plant communities can be described as areas where associated species thrive in conditions in which they are evolutionarily adapted. The right plant for the right place occurs naturally in response to environmental conditions such as light exposure, soil characteristics, and salinity levels. New York City is a highly altered landscape, yet many native plants have maintained their community structure in natural areas and even evolved to reclaim some of the built landscape. The relative health of habitats within New York City varies greatly and ecosystem function is highly dependent on the response of plants to the environmental conditions. Through adaptation, many tough native plant species have co-existed alongside the ever-increasing human population and the effects of pollution, compaction, urban rubble, and fragmentation, and are therefore more suited to the vaired conditions of our ecosytems.

The ecosystems listed within this manual contain common plant communities that can still be found throughout the five boroughs. To fully understand the possible values and limitations for landscape design, we encourage designers to examine the ecosystem context in which a given species naturally occurs. Its natural habitat can provide many clues about the conditions under which a species thrives. Furthermore, while climate change is leading to increased episodes of high rainfall, seasonal droughts are becoming more extreme. Even when a species is ecologically appropriate to a site and will most likely require less maintenance in the future, new plantings require the appropriate attention to weeding and watering, especially during the one-to-two year establishment period.

The lists in this section provide suggestions, but are not infallible guidelines, nor are they exhaustive. Consult the GNPC and the recommended resources within the References section for additional information on appropriate plants for various designed and restored landscapes. The native flora of New York City may not be what Henry Hudson encountered in 1609, but in choosing the right species for our restoration efforts and landscape designs, we can complement the native species that still naturally exist.

A. Coastal Communities

Coastal regions are characterized by dynamic landforms and processes because they are the juncture between the land and ocean. Features such as dunes and wetlands are dynamic systems impacted by storms, sediment supply, and sea-level change¹. Urban coastal regions often do not have the same literal or metaphorical space to change as they have in the past because of permanent alterations to the landscape to accommodate and protect high-density human populations. The effects of hurricanes and more frequent storms, combined with higher sea levels, are putting New York City's low-lying coastlines at risk. Restoration of our coastal plant communities and an effort to design with nature determines the long-term success and protection of coastal property and economic investment.

MARITIME BEACH/DUNE

Maritime beach/dune communities are dominated by salt-tolerant grasses and herbs. The sand is relatively unstable at the ocean-fronting beach and a limited number of plant species can survive in these harsh conditions.

Examples Include: Plumb Beach (BK), Far Rockaway (QU), and Conference House (SI).

MARITIME OAK FOREST

This oak-dominated forest is typically found near a marine community, such as a salt marsh or at the edge of a back dune. These plant communities are heavily influenced by the coastal processes including salt spray, high winds, flooding and sand deposition. The canopy may be stunted due to these processes and the understory is usually thick with a dense shrub layer and vines.

B. Wetland Communities

TIDAL WETLANDS

Tidal wetland habitats occur in low-lying areas along the coast where plants can tolerate daily inundation by the tides. Only about 4,000 acres of salt marsh still exist around New York City. By 1950, over 20,000 acres were destroyed after wetlands were filled with trash and construction debris².

LOW SALT MARSH

The low salt marsh is a tidal marsh zone characterized by daily flooding. The term "low" refers to the elevation of the land which occurs between the mean sea level and mean high tide. Very few plants in our region can tolerate this depth, duration, and frequency of flooding by salt water; the dominant species in this ecosystem is *Spartina alterniflora*, smooth cordgrass.

<u>Examples Include:</u> Pelham Bay Park (BX), Marine Park (BK), Four Sparrow Marsh, (BK), Inwood Hill Park (MN), Alley Pond Park (QU), Sawmill Creek (SI).

Recommended Plants:

Graminoids

Spartina alterniflora Smooth cordgrass
Spartina cynosuroides Big cordgrass

HIGH SALT MARSH

The transition from the low marsh to the high marsh occurs approximately at the mean high water mark. The high marsh, which extends to approximately the the mean high high water line, is flooded monthly during spring tides and in frequent coastal storm events. The high salt marsh community includes plants that tolerate brackish waters.

<u>Examples Include:</u> Pelham Bay Park (BX), Marine Park (BK), Four Sparrow Marsh, (BK), Inwood Hill Park (MN), Alley Pond Park (QU), Sawmill Creek (SI).

Symphyotrichum tenuifolium Perennial saltmarsh aster
Teucrium canadense American germander

Shrubs

Baccharis halimifolia Eastern baccharis

Iva frutescens Marsh elder

FRESHWATER WETLANDS

A non-tidal, freshwater wetland occurs in low-lying areas along streams and other bodies of fresh water that are subject to flooding. This may include isolated depressions that collect surface water, as well as areas with high groundwater tables. Wetland forests are plant communities which occur in poorly drained depressions on inorganic soils; their water levels fluctuate seasonally and usually drop in mid to late summer. Only about 2,000 acres of freshwater wetlands remain within the five boroughs from the hundreds of thousands of acres that date back to the Industrial Revolution³.

³ Luttenberg, D., Lev. D., and Feller, M. (1993). *Native species planting guide for New York City and vicinity*. New York, NY: City of New York, Department of Parks and Recreation.

SHALLOW EMERGENT MARSH

A shallow emergent marsh occurs on mineral soils that are more well-drained than a deep emergent marsh and have water depths from 6" to 3'. Shallow emergent marshes can be considered wet meadows, gradually sloping shores of ponds, lakes, and streams, or temporarily flooded drainage swales.

<u>Examples Include</u>: Seton Falls (BX), Prospect Park (BK), Flushing Meadows – Willow Lake (QU), Blue Heron (SI), High Rock (SI).

DEEP EMERGENT MARSH

A deep emergent marsh occurs on mineral soils or fine-grained organic soils (muck or well-decomposed peat) with water depths that varies from 6" to 6'. Most examples of this ecosystem in New York City are manmade impoundments or have been restored from naturally occurring, degraded habitats.

<u>Examples Include</u>: Van Cortlandt Lake (BX), Canarsie Beach Park (BK), Central Park – Turtle Pond (MN), Baisley Pond (QU), Long Pond (SI).

SCRUB SHRUB

A Scrub Shrub is an inland, freshwater wetland that is dominated by woody plant species less than 20 feet tall. These swamps occur along the shores of ponds, lakes, or rivers and in wet depressions and valleys. The substrate is usually a mineral soil or muck. Seasonal fluctuations in the water levels support a diverse flora and fauna.

Examples Include: Seton Falls (BX), Alley Pond (QU), High Rock (SI), Siedenburg Park (SI).

FLOODPLAIN FOREST

This hardwood forest community occurs on mineral soils in low-lying areas near stream or river floodplains. Usually, these areas are regularly flooded in the spring. Small stream floodplain forests in catchments dominated by small watersheds are less disturbance prone than river floodplain forests where major floods through these areas can scour the landscape or deposit significant sediment.

Examples Include: Bronx River Corridor (BX), Willowbrook (SI).

BOTTOMLAND FOREST

In addition to the NYNHP Floodplain Forest ecosystem, the US Forest Service classifies a deciduous forest that occurs between the floodplain forest and a true upland as a Bottomland Forest⁴. These forested wetlands are seasonally flooded and often characterized by varying elevations and land forms. The changing soil elevations and hydrological conditions support diverse vegetation.

Examples Include: Bucks Hollow (SI), Long Pond (SI), Reed's Basket (SI).

RED-MAPLE HARDWOOD SWAMP

This ecosystem has red maple (*Acer rubrum*) as the dominant canopy tree or as a co-dominant species with other mixed hardwoods. A common community throughout NYC historically, it occurs in poorly drained depressions, usually on inorganic soils⁵. The landscapes can vary in elevation and duration of standing water thought the year.

<u>Examples Include</u>: Bronx Park (BX), Alley Pond (QU), Clay Pit Ponds (SI), Bloomingdale (SI) Bloodroot Valley (SI).

C. Successional Communities

Succession is a natural process that occurs on the landscape after a major disturbance such as farming, logging, fire, or flood. Herbaceous plants typically dominate these ecosystems, along with pioneer shrub and tree species. Many non-native species thrive in these communities, but native plants have adapted to compete and therefore are key players in maintaining balance in the constant battle of invasive plant management. Early successional habitats are important transitional plant communities that precede forested landscapes in natural succession. This never-ending process is shaped by the environment of the site and the species available in the natural seed bank or by seed dispersal.

SUCCESSIONAL OLD FIELDS AND URBAN LOTS

Successional old field/urban lots are home to some of the toughest native plants of New York City. These plants can thrive in areas with low nutrient levels, low permeability, a minimal amount of organic matter, high pH, and high salinity levels resulting from urban fill and runoff. Many may see these plants as "weeds" growing out of concrete cracks, but these pioneer species can survive in the most severe landscapes, providing important ecosystem services.

Examples Include: Van Cortlandt-Vault Hill (BX), Marine Park (BK), Central Park-North Woods (MN), Idlewild (QU), Mount Loretto (SI).

SUCCESSIONAL SHRUBLAND

This ecosystem is a shrubland that occurs on sites that have been cleared or otherwise disturbed, and has at least a 50% shrub cover. Pioneer tree species, such as the gray birch (*Betula populifolia*) and the red maple (*Acer rubrum*) are usually mixed in with this young habitat. Forbs, graminoids, and ferns provide a great ground cover for a diverse fauna.

Examples Include: Marine Park (BK), Mariner's Marsh (SI).

OAK OPENING

Oak Openings were originally characterized as openings that occurred as gaps within extensive oak-hickory forests. This grass-savanna community flourishes on these very well-drained sites. They can also be described as knobs or hilltops with shallow soil over rock outcrops or sandy to gravelly soils. Fragmentation throughout New York City's remaining forests restricts areas where this plant community still naturally occurs. Woody species continue to creep in from the surrounding tree and shrub lines, unless maintained to keep a meadow-like open character. Generally trees should not be part of the planting plan, however if necessary they should be planted much more sparsely than in other forested projects.

<u>Examples Include</u>: Pelham Bay-Orchard Beach Meadow (BX), Central Park-North Woods (MN), Clove Lakes (SI).

SUCCESSIONAL MIXED HARDWOODS

A successional mixed hardwood forest is dominated by pioneer tree species such as poplars, birches, maples, and cherries. These sun-loving species grow fast and quickly colonize a disturbed area. As the canopy closes, more shade-tolerant species move into the understory and tree seedlings of the climax forest, such as oak or hickory, may appear.

Examples Include: Seton Falls (BX), Prospect Park (BK), Central Park (MN), Kissena Park (QU), Heyerdahl Hill (SI).

SERPENTINE BARRENS

The plant communities of the serpentine barrens are a state and globally rare habitat because of the geographically restricted serpentine bedrock they are found on. Serpentine bedrock is light green bedrock that is thought to have been forced from the earth's core 450 million years ago during plate shifting activity. The green color is due to the high concentration of magnesium

in the rock⁶. Staten Island is the only borough where you can find remnants of this unique habitat. The open grass-savanna communities thrive in the nutrient-poor soils but most sites have been obliterated by forest succession in the absence of wildfire and later, by conversion to urban uses⁷.

Examples Include: Seaview Meadow (SI).

SUCCESSIONAL MARITIME OAK FOREST

A maritime forest naturally succeeds a maritime shrubland if it is left undisturbed. A minimal amount of herbaceous material at ground-level is able to survive. The dense shrub layer and a closing canopy shades out many of the herbaceous species. Please refer to the Coastal Communities section for the detailed plant lists for this ecosystem.

D. Upland Forest Communities

Upland forest communities are plant communities characterized by a tree canopy cover of at least 60%. The majority of the forests in the New York City area occur on moist, well-drained soils.

MIXED OAK-HICKORY FOREST

This hardwood forest occurs on well-drained sites with loam or sandy loam soils. These communities can be found on ridgetops, upper slopes, or on slopes in the coastal lowlands. The tree canopy typically contains hickory species mixed with two or more species of oaks.

<u>Examples Include</u>: Pelham Bay-Hunter Island (BX), Prospect Park (BK), Inwood Hill (MN), Forest Park (QU), High Rock (SI).

RICH MESOPHYTIC FOREST

The Rich Mesophytic Forest is home to some of New York City's most stunning plant communities. The rich, seasonally-moist, well-drained soils are favorable to spring ephemerals and the culturally significant sugar maple (*Acer saccharum*). The acidic qualities of the soils are maintained by the variety of oak species typical to these communities.

OAK-TULIP TREE FOREST

This mesophytic forest is a mixture of hardwoods and softwoods. The dominant species of oak and tulip poplar are usually joined by black birch, beech, or red maple. Moist, well-drained soils support a diverse understory of shrubs and herbaceous flora. Tulip poplars, with their very straight trunks, can reach over 100 feet tall. Their magnificent form helps to bring a natural giant to the famed New York City skyline.

<u>Examples Include</u>: Pelham Bay-Hunter Island (BX), Prospect Park (BK), Inwood Hill (MN), Forest Park (QU), Bloomingdale (SI).

CHESTNUT OAK FOREST

This hardwood forest is situated on well-drained sites on the coastal plain. Tree canopy species diversity is limited to two or three oak species and red maples. Historically, the American chestnut thrived in these habitats until the chestnut blight decimated the populations. American chestnut sprouts can still be found in the understory today. The understory consists of ericaceous shrubs such as black huckleberry (*Gaylussacia baccata*) and blueberry (*Vaccinium pallidum*).

Examples Include: Van Cortlandt Park (BX), Forest Park (QU), Deere Park (SI).

Planting Near Natural Areas

The natural areas of NYC act as refuges for diverse wildlife. They represent the most valuable ecosystems in the ever-changing urban landscape, and though considerable effort is made annually to conserve these areas, they are continually threatened by the invasion of non-native species, development, and climate change. The edges of forests and other natural areas face the greatest risk. Non-native plant species easily colonize edges in part because light resources are widely available. Once established along the edges, non-native plants can spread into habitat interiors, reducing species diversity, and changing the way the whole ecosystem functions.

Many of NYC's Natural Areas abut private property. This is particularly true in Staten Island and the Bronx, which contain some of the largest overall acreage of parkland in the five boroughs. Making wise native planting choices for landscape design on these private properties helps prevent edges of natural areas from becoming degraded habitats or corridors for invasive plants. Additionally, these properties can provide ecological connectivity with neighboring sites and between larger, publicly protected natural areas. This guide can and should be used to help determine the best species for landscaping projects adjacent to our natural resources.

Many of the private properties adjacent to natural areas, particularly on Staten Isalnd, fall into one of the typologies listed below. The following lists can be used as a starting place for planning a project on these private properties. They offer a broad palette of species that are appropriate for clearly defined habitats and site typologies. As previously mentioned, the Greenbelt Native Plant Center grows many of these species and their staff has a wealth of knowledge regarding the right native plants for these areas. Note that as sea levels rise, particularly in flat, low-lying coastal habitats, areas influenced by tide or salt spray might change.

FOREVER WILD

Established in 2001, the Forever Wild program identified the most ecologically valuable areas within the NYC Parks system for protection, conservation, and restoration. As the entity responsible for managing over half the natural areas in the City, it is NYC Parks' policy to protect natural areas under our jurisdiction and manage them over time so that they continue to provide benefits for future generations. One of these best management practices is the mandated use of native plants in city-owned natural areas by Local Law 11 (2013) (§ 18-141 NYC Admin. Code). In general, the Forever Wild management guidelines work in concert with legal regulations and policies to emphasize natural resource protection in a comprehensive and integrated way. Forever Wild maps were updated in 2018 to include the latest information about New York City's natural areas, correct boundaries, and to reflect significant technological advances in geospatial data management.

From a bird's eye view, New York City is a mosaic of green spaces, and even intermittent assemblages of native plant species can facilitate the movement of native pollinators and seed dispersers throughout our diverse landscape. Genetic variation and connectivity are critical to the population health of native plant communities. The Forever Wild Program was established to help maintain reservoirs of genetic diversity and connectivity for our native flora. Natural areas in New York City are an irreplaceable element of our cultural heritage. The increased use of native plants in appropriate settings creates a landscape vital to both contemporary and future New Yorkers.

Invasive Plants in New York

Invasive Species

An invasive species is defined as an organism that is not native to the ecosystem under consideration and whose introduction causes or is likely to cause harm to the environment, economy, or human health⁸. Invasive plants harm the environment by displacing native flora, which in turn, impacts wildlife and other species dependent on the native flora. They impact ecological stability and biodiversity by disrupting such processes as hydrology, nutrient cycling, natural succession, wildfire regime, and soil erosion.

Invasive plants are not unique to NYC, but these species have damaged thousands of acres of NYC Parks' natural lands. The Natural Areas Conservancy's recently published Forest Management Framework estimates it costs between \$6,000 and \$42,000 per acre to restore forests impacted by invasive species. By adhering to the regulations of New York State by prohibiting the planting of invasive plants, the City's economic burden of managing these species will be reduced and the ecological resilience will increase through promoting native biodiversity and functional ecosystems. NYC Parks' Division of Forestry, Horticulture and Natural Resources, along with our dedicated volunteers, makes significant strides in reversing these invasions and restoring our natural areas every year.

New York State Regulation

In 2012, the Governor of New York State signed into law the Invasive Species Prevention Act, which prohibits or regulates the transport and sale of certain invasive species⁹, including plants. This act requires the New York State Department of Agriculture and Markets and the New York State Department of Environmental Conservation to develop regulations concerning the sale, purchase, possession, introduction, importation, and transport of these species.

The New York State law was passed in consultation with a broad range of stakeholders including ecologists and representatives from the nursery and landscape industry. Under the regulatory framework, a given species is examined through both a scientific and socioeconomic assessment. Criteria including ecological impact and distribution, biological traits, dispersal ability, and difficulty of control are among those characteristics assessed. Cultivars of these species are assessed separately.

Species exceeding certain thresholds as determined by the ranking protocols are placed in one of two categories. Those species not listed in one of the categories below are considered unregulated.

_

⁸ ECL §9-1703 (10).

⁹ Under the law, invasive species is defined as (a) nonnative to the ecosystem under the consideration; and (b) whose introduction causes or is likely to cause economic harm or harm human health, Environmental Conservation Law §9-1709 as amended.

<u>Prohibited</u> – Unlawful to possess with the intent to sell, import, purchase, transport, introduce, or propagate except under a permit for disposal, control, research, or education.

<u>Regulated</u> – Possession, sale, purchase, propagation, and transport are legal, but these species may not be introduced into a free-living state on public land or in natural areas.

This Act also directs the agencies to develop both a permit process and specific lists of species, which are subject to varying degrees of regulation. Towards this end, protocols have been developed to determine if a species' tendency toward invasion warrants regulation.

The list below does not include all invasive or potentially invasive plant species, but it does include those that are currently regulated by the state. These lists are excerpted from the final adopted New York State regulations. Cultivars of these species are regulated in the same manner as the parent species until a separate cultivar assessment is performed. Several of the species below have had updates to their taxonomic name, the full list of alternative scientific names can be found on the webpage linked above.

What Does This Mean for New York City?

This law is primarily intended to exclude listed plants from commerce, so they are no longer available for purchase or planting. Ultimately, it bars certain plants from use in public landscapes. Residents and agencies are no longer able to specify Prohibited plants in capital project designs, plant them in ornamental beds on private or public property, grow them in greenhouses, or offer them for sale. There is a permit process for disposal, control, and research activities involving some of these species.

Problematic Species

There are a number of additional species that have demonstrated tendencies to escape from cultivation and are naturalizing throughout parks and natural areas. The species on this list are recognized by professionals and institutions in the tri-state area, and/or nationwide, as potentially damaging to our natural systems. While use of these species is not likely to be regulated by State Law, caution must be exercised when planting these near a Forever Wild or other natural area.

Native Alternatives to Common Invasive Plants

Horticultural value is one of the many reasons why non-native plant species have been imported. These plants usually have some desirable characteristic such as form, fall color, or attractive fruit. As indicated earlier in this guide, some of these species have become invasive. There are, however, native plants which can provide similar horticultural characteristics.

The species listed in this section are alternatives to invasive plant species that are either regulated and prohibited by New York State, or are considered problematic when planted near natural areas. They have been chosen because they can provide a similar form, growth habit, or other desirable horticultural characteristics. A number of alternatives have been provided for each invasive species to best accommodate a variety of growing conditions. This is not an exhaustive list, and a landscape architect or designer may suggest additional species.

Stormwater Tolerant Plants

New York City has embarked on a major program to use green infrastructure (GI) to reduce combined sewer overflows and the flow of pollutants in stormwater into the city's waterbodies. Green infrastructure, including Green Roofs, Right-of-Way (ROW) Rain Gardens, Stormwater Greenstreets, Rain Gardens, and Retention Ponds, captures stormwater at its source, before it enters the city's stormwater systems. The design and construction of planted GI projects vary greatly by their location and by the goals for stormwater capture. For example, ROW Rain Gardens need to be designed with plants that can survive periodic inundation, drought, and harsh roadside conditions. This guide has been developed to help users identify plant species that are best suited for each specific location in the urban landscape. Within the Native Species Description section, species have been designated according to the specific stormwater management systems they are best suited for. Many of the stormwater species that are in the following lists are known to perform well based on field testing and practical experience. Many of these species are also proven performers in a variety of different soil conditions. However, in the interest of promoting innovation and diversity, some species have been included in this list based on the premise that their naturally occurring habitats and conditions suggest that they would make them excellent candidates for GI (i.e., species that are found in habitats that are seasonally flooded). These "suggested" species are annotated with an asterisk (*). In the lists below, the zones are defined by the following categories: a) inundation, b) slopes, and c) upland. The inundation zone is the plant zone at the bottom of the soil depression of a rain garden. After a rain storm, this zone is inundated with water. Inundation typically lasts for more than 24 hours. This zone is best planted with species that can tolerate both occasional inundation and dry periods. The slopes zone occurs along the slope of a rain garden, which is best planted with species that can survive in a variety of soil moisture conditions. The upland zone typically occurs above the slope and around the rain garden.

Ferns

Polystichum acrostichoides*Christmas fernSlopesThelypteris noveboracensis*New York fernSlopesThelypteris palustris*Marsh fernInundation

In addition to the species list above, the following ecosystems can be referenced for selecting other species that may be suited for green infrastructure projects.

- O Floodplain Forest, Bottomland Forest, Red-Maple Hardwood Swamp, and Wetland Communities can provide a range of suitable species for green infrastructure projects, though attention to the salt and drought tolerance of individual species should be considered. These species are best used in the lowest areas of rain gardens that receive the most runoff and would be periodically inundated. Many of these companion plants offer quality resources for pollinator habitat throughout every season.
- Maritime communities are often a good starting point for urban green infrastructure sites, due to their tolerance of salts, high sand content in soils and tolerance of periodic inundation. Take note that green infrastructure sites can also be dry during non-rainy seasons, so plants selected should also have a range of drought tolerance.

- Shrub Swamp and Successional Shrubland offer a range of species that tolerate seasonal fluctuations in soil moisture, making them ideally suited to rain gardens and other stormwater capture installations. Successional Shrubland species often exhibit greater urban tolerance, and so are especially suited to road runoff projects.
- Grasses and herbaceous species from Mixed Oak-Hickory Forest and Maritime
 Grasslands communities work well on green roofs, due to their tolerance of winds, shallow
 soils and drought.

Species Least Preferred by Deer

The native ecosystems and horticultural plantings in the boroughs of the Bronx and Staten Island are experiencing extreme pressure by white-tailed deer (Odocoileus virginianus). Whitetailed deer have no natural predators in New York City and hunting is prohibited. Each year the population of deer increases and therefore so does the population's demand for food. There are no plant species that are truly deer resistant; white-tailed deer are herbivores and if they are hungry, they eat any plant material - even tree bark. Deer have developed preferences for the native species they have co-evolved with, but there are a plethora of species that are considered to be less desirable, or that they may ignore in their grazing patterns. For these species, browsing by deer may only occur as fresh new growth appears on plants and are then ignored for the rest of the season. Planting with a high diversity of species minimizes the impact that any deer browse has in overall garden design. Aesthetically pleasing native species, which minimize horticultural inputs and maximize the benefits to pollinators and the greater ecosystem, can be used in highly designed landscapes or to offer a more natural look to a landscape. Many ferns and grasses are rarely damaged by deer and strong scented perennials are often a avoided. Additional measures, such as deer fencing, may be essential to ensure complete protection of the landscape.

FERNS

Ferns are a group of plants that are generally not preferred by deer. Fiddleheads, the new spring growth of ferns, may experience some browse. The most likely plant specimens to be affected are those along high traffic deer paths. This unfortunate collateral damage can be mitigated by planting strategically if traffic patterns are observed.

GRAMINOIDS

Grasses make up less than 10% of a deer's annual diet. Mature grass specimens are less palatable to deer because of the coarse structure of the cellulose in the blades, which is harder to digest. Grasses are also lower in nutrients when compared to forbs or woody plants. Fresh new growth on clumping grasses may experience some browse and cool season species like wild rye (Elymus spp.) are foraged. Many species within the sedge family (Cyperaceae) are ignored by deer; listed below are a few popular choices.

FORBS

Forbs are among the most highly desired group of plants for deer. Forbs are highly nutritious, easily digestible, and available throughout each growing season. Forb species most likely to be avoided are those that are strongly scented, like a species from the mint family (Lamiaceae), or those with a coarse texture.

WOODY SPECIES

Woody species are a favorite among deer for their fruits and seeds as well as the tender leaves and twigs of new growth. Shrubs and trees are targeted every season as a potential food source. Some species are avoided because of their toxicity level or coarse texture. Forest regeneration is increasingly threatened by the presence of deer and their preference for tree nuts, fruits, and tender saplings.

Planting in the Built Environment

Plant communities found in the built environment include unique assemblages of species that tolerate disturbance and stress. Soil composition, microclimate, and resource availability are highly dependent on the land use history of a project site and impact plant survivability. Just as the constructed parts of our city vary from developed highrises to abandoned lots, the plant species thriving in our city vary by niche, from streetscapes and plazas to open lots and privately owned parks or yards.

The palette of our natural plant communities can be used to help select the right plant species for the right urban place. Understanding the conditions that these plants naturally occur in reveals the compatibility of a particular species to a project's site conditions.

Often when planting in built environments, plant size selection and seed mixes can be critical to the success of the design. Consultation with experts can help ensure the proper quantities, spacing, and methods for installation are applied when using native plant species. For example, the diversity of a native seed mix and the proper ratio of grasses and forbs differs by habitat and site conditions.

ALTERED LANDSCAPES

Highly altered landscapes, which are common to urban areas, can be some of the most challenging sites to select plants for. Some of the many issues that need to be considered when planting in urban sites are pollution, compaction, poor soils (i.e., nutrient deficient, contaminated, high pH), runoff, dought, and maintenance. These conditions may lead people to fall back on a palette of mostly non-native plants because of the belief that "nothing else will grow there." In reality, many native pioneer species already successfully inhabit and thrive in abandoned lots and rail lines, cracks in the concrete, and roadsides.

- Many of the species found in Successional Communities Old Fields and Urban Lots, are
 the ideal species to consider for challenging sites. Designers should consider these species
 for a variety of urban parks.
- O Poor soils with low nutrients, or other soils with high content of magnesium or other metals, where remediation or restoration is not possible or desired, can prove challenging for landscaping. Plants from the Serpentine Barrens community may be appropriate, given their adaptations to thrive in low-nutrient soils close to bedrock. Their native soil conditions are only found on Staten Island; however, these plants can be considered for use in other disturbed soils.
- For new parks or sites with minimal canopy, Successional Mixed Hardwoods provide a range of species that are hardy, establish quickly, and tolerate a range of soils. Utilizing a successional planting approach to reach a desired climax habitat is necessary for the long term sustainability of a healthy ecosystem.

CLOSED CANOPY PROJECTS

Many established parks have a dense tree canopy that can limit the amount of sun and nutrients that reach the forest floor. In projects that aim to expand understory species diversity, there are a range of opportunities to use native plants. Knowing the habitat your project is situated within can help guide you to species that are suitable for the existing conditions.

- In openings in the established canopy that are being expanded into planting beds, the species of the Oak Opening community would be appropriate and most beneficial to the fauna traveling in between the fragmented forest.
- In areas within the established canopy, the species of Rich Mesophytic Forest, Oak-Tulip
 Tree Forest and Chestnut Oak Forest are well suited to the topsoil specified in Parks'
 projects and provide a wide range of understory and herbaceous diversity.
- For areas with greater salt exposure, species from Maritime Oak Forest and Successional Maritime Oak Forest may be well suited, though this community is dominated by a shrub layer and offers few herbaceous selections.
- o For greater drought tolerance, species listed in the *Mixed Oak-Hickory Forest* ecosystem have adapted well to shallow soils, low water, and exposure.
- Creating vegetative buffers near or around natural areas can help protect and enhance high quality habitat, while helping to facilitate pollinator connectivity. The *Natural Area* typologies section, which include coastal, bluebelt and brackish habitats, as well as woodland and open edges, recommends species appropriate for vegetative buffers.

INVADED WETLANDS

Many of New York City's wetlands were once fill or dump sites that drastically changed the soil makeup, permeability, and the natural plant communities that existed there. Aggressive invasive species such as common reed (*Phragmites australis*) often invade these degraded marsh systems. Restoration in these invaded wetlands is a long-term process and requires a multi-pronged approach that includes using appropriate native plant species. These species should be gradually introduced during the treatment process to help colonize newly disturbed land, remediate the soil, and compete with the aggressive invasive species. In coastal areas in particular, sea level rise might increase tidal inundation and help surpress *Phragmites*. In these locations planting salt marsh species might aid in the invasive plant control.

STREET TREES AND TREE BEDS

Street trees are a part of the fabric of New York City. A tree-lined street improves the overall health of a neighborhood and helps to beautify a concrete landscape. The conditions that street trees grow in are harsh and although the design of tree beds are improving, there are critical characteristics that a species must have to survive. Trees on the roadside have to endure salt spray and drought conditions. The open surface area on the ground that is permeable to water is limited in a tree bed, but with the addition of planted herbs and grasses, soil and moisture are retained in the pit. Even trees that have a larger surface area of lawn, in a median or a greenstreet, still benefit from being drought tolerant considering the limited amount of natural soil area and infiltration in these sites.

TREE LAWNS

Tree lawns can be considered high maintenance due to the amount of fertilizer, water, and mowing required to keep them aesthetically pleasing. Incorporating perennial layers in a naturalistic design helps cut costs, diminish the mowing schedule, and improve the habitat value of the landscape.

Native Plant Descriptions

Successful plant communities are usually composed of a combination of various species in unique proportions. These proportions characterize the various ecological communities described in the guide. For instance, trees are largely absent from coastal dune communities, but form the dominant vegetation in a bottomland forest. Effective planting strategies can be based on supplementing existing vegetation to replicate the plant communities of naturally occurring ecosystems, depending on careful analysis of soils, light conditions, and hydrologic resources. It is important to consider the mature size of selected plants to best determine the appropriate spacing.

The following section contains descriptions of common native species representative of the existing metropolitan flora all of which are suitable for planting in the five boroughs. All of the species in the various lists above can be found in this section. We have compiled research on many important ecological characteristics for the species in this guide. However, information on every characteristic is not available for every species and we note this where applicable. If you are looking for more information about a specific species, please consult staff at the Greenbelt Native Plant Center, your local Landscape Architects, or one of the online resources in the resources section of this guide. In addition to species that are not native to this area, a number of species in the flora of New York City are considered rare, threatened, or endangered. It is not recommended that these species are planted, as a particular protocol needs to be followed to properly reintroduce them to the landscape; these species have not been included in this guide.

Species names that have been denoted with a (†) are <u>not</u> available from the Greenbelt Native Plant Center. Unavailability is attributed to one of three factors: germplasm is not available in the seed bank, naturally occurring populations are not large enough for collection, or populations in the metropolitan region (defined as a 50-100-mile radius around the city) have not been located.

Some of the information presented is technical in nature, so to assist the reader the following tables are provided to clarify the data.

Wetland Classification:

Indicator Code	Indicator Status	Designation	Comment
OBL	Obligate Wetland	Hydrophyte	Almost always occurs in wetlands
FACW	Facultative Wetland	Hydrophyte	Usually occurs in wetlands, but may occur in non-wetlands
FAC	Facultative	Hydrophyte	Occurs in wetlands and non- wetlands
FACU	Facultative Upland	Nonhydrophyte	Usually occurs in non-wetlands, but may occur in wetlands
UPL	Obligate Upland	Nonhydrophyte	Almost never occurs in wetlands
NC	Not classified		Species has no wetland classification

Salt Tolerance:

Designation	Definition
High tolerance	The plant naturally exists in habitats in close proximity to
	salt water and can tolerate being flooded with salt water
	either daily or occasionally.
Tolerant	Can be exposed to salt spray or occasional salt water
	inundation. Good candidates for street edges, where
	winter road salting occurs.
Moderately tolerant	Can be exposed to salt spray, but may be intolerant to salt
	water inundation or coastal flooding.
Low tolerance	Minimum exposure to salt spray and intolerant to salt
	water inundation.
Intolerant	Not tolerant to salt water inundation or salt spray.
Insufficient research to determine	Current research is not available or has not been found to
	determine its tolerance to salt. Consider the plants' natural
	habitat and its likely association with salt as a potential
	indicator.

Soil pH

рН	Soil Category
<3.0	Severely acidic
3.01 – 4.0	Strongly acidic
4.01 – 5.5	Moderately acidic
5.51 to 6.8	Slightly acidic (optimum for many plants)
6.81 – 7.2	Near neutral (optimum for many plants)
7.21 – 7.5	Slightly alkaline (optimum for many plants)
7.51 – 8.5	Moderately alkaline
>8.5	Strongly alkaline

Shade Tolerance:

Designation	Definition
Shade tolerant	Can handle fully shaded habitats, ranging from 2-25% sun
	exposure
Tolerant of partial shade	Can handle limited shade, 25-50% sun needed
Intolerant	Needs full sun, 50-100% sun exposure

Stormwater Tolerance:

Designation	Definition
Green Roof	Plantings on built roof structures, including both 'extensive green
	roofs' (plantings with shallow depth) and 'intensive green roofs'
	(greater soil depth that can sustain deep rooted herbaceous plants
	as well as trees and shrubs).
ROW Rain Garden (*)	Relatively small rectangular planted areas in the street landscape
	that capture stormwater from the street, usually in the sidewalk
	where street tree beds are also located.
Stormwater	Similar to the ROW Rain Garden but larger and more varied in
Greenstreet (*)	shape. These larger planting beds along the roadway or in the street
	median allow for more options of species that can withstand varied
	inundation levels and may be larger in habit.
Retention Pond	A pond that captures and holds stormwater, typically with a planted
	edge.
Rain Garden	Planted area in parklands or yards that capture stormwater and vary
	in shape and size.
Unsuitable	This species is not appropriate for stormwater systems.
Insufficient research to	Current research is not available or has not been found to determine
determine	its tolerance to salt. Consider the plants' natural habitat and if
	necessary, its likely association with salt as a potential indicator.

^{*} Within the Native Plant Descriptions section, species that have been field tested for these systems have not been distinguished from those that have been suggested based on their naturally occurring habitats and the conditions they tolerate. Please refer to the lists in the Stormwater Management section above for specific species that have been field tested for ROW Rain Gardens and Stormwater Greenstreets.

Ferns

Ferns add texture to the ground layer. There are species adapted to sun or shade, wet or dry conditions, and various heights and degrees of vigor. Most ferns in New York State are protected under the heading "exploitably vulnerable". These plants may not be rare, but are susceptible to overharvesting if not protected. Being informed on where your plants have come from can help in the protection of the natural populations of these important species.

Vines

Vines, either woddy or herbaceous, can climb vertical structures, provide erosion control on slopes, or create a groundcover. Consider the surface or area you want a vine to colonize when planting (i.e. they can provide shade or help capture stormwater over impervious surfaces). Most native vine species are companion plants and are not considered aggressive; they do not strangle other plants in the landscape.

Top: Parthenocissus quinquefolia (Virginia creeper) Right: Dioscorea villosa (Wlld yam)

Trees

Trees, single-stemmed woody plants with a mature height generally over twenty feet, are dominant landscape elements. They perform a number of functions in a park or residential setting, such as providing shade, habitat for wildlife species, and regulating the climate. Because plants do not adhere to the definitions we place on them, some species grow with a more shrub like habit (i.e. multi stemmed) but at a height more like trees (i.e. over twenty feet). As a result some species are often

considered both a tree and a shrub. Consideration should be given to the mature size of a species, as well the ornamental qualities of fruit, form, bark, floral display, and fall color.

Balsam fir Abies balsamea†

Wetland Soil: **FACW** pH 5.5-6.5

Indicator:

Form/Color Conical; 50'-75' tall; 50'-75' wide spread; Stormwater ROW Rain garden, Stormwater

greenstreet, Retention pond, maroon green in spring; dark green in Tolerance: Inundation

summer; deep scarlet red in fall.

Urban Sensitive to soil compaction, tolerant of sulfur dioxide, performs Tolerance:

well in the right of way.

Habitat: Swamp and floodplains forests, second

bottoms, alluvial flats, rich mesophytic

Ecosystem Very high wildlife value for Services: songbirds, waterbirds, upland groundbirds, small mammals, and

hoofed browsers.

Tolerant of flooding and saturated soil Hydrology:

up to 25% of growing season.

Horticultural Scarlet red color in fall.

Intolerant

Value:

Shade

Tolerance:

Compatibility:

Salt Tolerant

Tolerance: Other: Used for in swamp forest

reforestation, flood plains, wetland mitigation, street tree; medium lifespan 125-175 years, fast

grower.

Northern red oak Quercus rubra

Wetland **FACU** Soil: pH 4.5-6.5

Indicator:

Form/Color 50'-75'; 75'-100' wide spread; distinctive

> bark with shallow furrows often compared to ski trails; blooms in May; ripe acorns September-October.

Stormwater ROW Rain garden, Stormwater

greenstreet, Upland Tolerance:

Urban Tolerant of soil compaction, tolerant of pollution, performs well in the Tolerance:

right of way.

Common in New York City forests; Appalachian oak-hickory forest; rich

mesophytic forest.

Ecosystem High wildlife value; acorns eaten by Services: birds and small mammals.

Hydrology: Deep, moist, well-drained soils; intolerant

of flooding.

Horticultural Yellowish to red fall color. Compatibility:

Value:

Habitat:

Salt Tolerant

Tolerance: Other: Used for restoring upland decidous

forests; park tree; street tree; long

lifespan; slow grower. Shade Tolerant of partial shade Tolerance:

Post oak Quercus stellata

Stormwater

Tolerance:

Ecosystem

Compatibility:

Services:

Wetland Soil: **FACU**

Indicator:

Form/Color Globular form; 35'-50'; 35'-50' wide

spread; dark red in spring, deep dark green in summer, yellow green catkins May-early June; acorns ripe September-

early October.

Urban Tolerance:

Habitat: Sandy ridges, dry rocky hillsides,

southern slopes.

Hydrology: Intolerant of flooding; tolerant of

drought.

Horticultural Dark red color in spring, golden yellow

Value: brown in fall.

Salt Tolerant

Tolerance:

Shade Intolerant

Tolerance:

Other:

Long lifespan of 200-300 years; slow grower. Used to reforest woodlands in sandy soils of coastal, back dune oak barrens, or

rocky uplands.

pH 4.6-6.5

species.

ROW Rain garden, Stormwater

greenstreet, Slopes, Upland

Intolerant of soil compaction.

Very high wildlife value; acorns

host to larvae of some butterfly

eaten by birds and small mammals,

Black oak Quercus velutina

Wetland NC Soil: pH 5.0-6.5 Indicator:

Form/Color Oviod and commonly globular; 75'-100';

75'-100' wide spread; bright crimson red in spring; yellow green catkins mid through late May; light red brown acorn

ripen September.

Stormwater ROW Rain garden, Stormwater

Tolerance: greenstreet, Upland

Clay and gravelly ridges, sand dunes,

nutrient soils.

Ecosystem

Tolerance:

Intolerant of soil compaction.

Habitat: Very high wildlife value for upland middle and upper slope forests with low ground birds, songbirds, hoofed Services:

browsers, and small mammals.

Urban

Hydrology: Very intolerant of flooding; moderately

well to excessive drainage; tolerant of

Horticultural Crimson red in spring, yellow to golden

Value: brown in fall. Compatibility:

Salt Tolerant

Tolerance: Other: Used for reforestation of upland

forest.

Shade Tolerant of partial shade

Tolerance:

Salix eriocephala

Missouri river willow

Wetland **FACW**

Indicator:

Form/Color

Soil:

Grows to 12';catkins April-May; fruit

May-June; fast grower.

Stormwater

Tolerance:

Retention pond, Rain garden,

Inundation, Slopes

pH 4.0-7.0

Urban

Tolerance:

Tolerant of soil compaction.

Habitat: Open, wet soil, pond edges, ditches. **Ecosystem** Services:

Low wildlife value.

Hydrology: Low tolerance for drought conditions;

high moisture use.

Horticultural Dark gray, scaly bark.

Value:

Compatibility:

Salt Intolerant

Tolerance:

Shade tolerant

Shade Tolerance: Other: Used for wetland reforestation and

mitigation in open habitats, pond edges, stream banks, and flood

plains.

Salix nigra **Black willow**

Wetland Indicator: OBL

Soil:

pH 6.5-7.5

Form/Color Columnar form; 35'-35'; 20'-35' wide

spread; yellow green in fall; yellow green catkins mid March- early April; green yellow strobiles late April-mid May. Stormwater Tolerance:

Retention pond, Rain garden,

Inundation

Urban

Tolerance:

Tolerant of fill soils, concrete debris,

and soil compaction.

Habitat: River margins, low lying lakeshore,

swamps, swales, gullies.

Ecosystem Services:

High wildlife value for songbirds, waterfowl, and small mammals.

Very poor to moderately poor drainage; Hydrology:

wet to moist; very tolerant of flooding.

Horticultural Yellow green fall color.

Value:

Compatibility:

Salt

Shade

Intolerant

Tolerance:

Other:

Very fast grower, used for restoring flood plain and riverbank

restoration; wetland mitigation.

Tolerance:

Intolerant

Sassafras Sassafras albidum

Stormwater

Tolerance:

Services:

Wetland Soil: **FACU** pH 3.8-7.0

Indicator:

Form/Color Conical and irregular form; 35'-50'; 35'-

50' wide spread; yellows, oranges, reds, and purples in fall, small clusters of bright yellow and sweet fragrant flowers

late April-early May.

Urban Intolerant of soil compaction. Tolerance:

Slopes, Upland

Habitat: Found in frequently burned open areas;

open woods, abandoned fields, dry

ridges and upper slopes.

Ecosystem Low wildlife for songbirds, host for

some butterfuly larvae.

Retention pond, Rain garden,

Hydrology: Very intolerant of flooding; well to

excessive drainage.

Horticultural Varying colors of yellow, orange, red, and purple in fall, foliage = 3 kinds of Value:

leaves.

Compatibility: Frequently forms colonies.

Salt Tolerant

Tolerance:

Shade Intolerant

Tolerance:

Other: Short lifespan 50-75 years.

Thuja occidentalis†

Arborvitae

Wetland **FACW** Soil: pH 6.0-8.0

Indicator: Form/Color

Conical; 50'-75'; 35'-50' wide spread; small red brown cone early through late May; tan brown to silvery gray eggshaped cone early August- February.

Stormwater Retention pond, Rain garden, Tolerance: Slopes, Upland

Urban

Tolerance:

Intolerant of soil compaction.

Habitat: Swampy areas, bogs, margins of lakes,

mesic coves, open rocky hillsides,

open rocky pastureland.

Ecosystem Services:

Low wildlife value for songbirds, waterfowl, and small mammals: browsed by small mammals and

white-tailed deer.

Hydrology: Tolerant of flooding; poor to well

drainage; wet to dry moisture levels.

Horticultural Dark green foliage turns yellow-green to Value:

brown in winter.

Compatibility:

Salt Moderately tolerant

Tolerance:

Shade Tolerant of partial shade

Tolerance:

Other: Long lifespan, fast to medium

grower.

American linden Tilia americana

Wetland Soil: **FACU** pH 6.5-7.5

Indicator:

Form/Color Ovoid;75'-100';50'-75' wide spread;

golden yellow in fall; clusters of pale yellow flowers late June-early July; tan brown samara September-October;

medium grower.

Ecosystem

Services:

Stormwater

Tolerance:

Urban Tolerant of concrete; intolerant of Tolerance: soil compaction, performs well in the

Very low wildlife value.

Unsuitable

right of way, minimal tolerance of

Habitat: Mesic ravines, coves, north and east

slope aspects, floodplain knobs, areas

of cool air drainage

Intolerant of flooding; moderate to well

drainage; average moisture levels.

Horticultural Golden yellow leaves in fall.

Value:

Hydrology:

Compatibility:

Salt Intolerant

Tolerance: Other: Susceptible to Verticillium wilt,

powdery mildew, leaf blight, canker. Shade tolerant

Shade Tolerance:

Tsuga canadensis Eastern hemlock

Wetland **FACU** Soil: pH 4.6-6.5

Indicator:

Broadly conical; 75'-100'; 35'-50' wide Form/Color

spread; coniferous evergreen; light yellow male cone and pale green female cone late May- early June; tan brown

cone September - January.

Stormwater Unsuitable Tolerance:

Ecosystem

Services:

Urban Intolerant of soil compaction,

for wildlife.

Tolerance: sensitive to ozone.

Habitat: Protected coves, mesic ravines, moist

cool valleys, north and east slope aspects, benches, hollows under cliffs.

Very intolerant of flooding; well to poor

drainage; wet to average moisture

Horticultural Dark green foliage year round.

Value:

Hydrology:

Compatibility:

Salt Intolerant

Tolerance:

Shade tolerant

Tolerance:

Shade

Other: Very susceptible to drought and

heat; susceptible to wooly adelgid; long lifespan; medium to slow

Intermediate wildlife value for

songbirds, small mammals, and

hoofed browsers; good winter cover

grower.

<u>Ulmus americana</u> American elm

Wetland FACW Soil: pH 6.6-8.0

Indicator:

Form/Color Globular; 75'-100'; 75'-100' wide spread; Stormwater ROW Rain garden, Stormwater

golden yellow in fall; small clusters of red brown flowers early-mid April; tan

brown samara May.

Tolerance: greenstreet, Inundation, Slopes

Urban Intermediate tolerance of soil

Tolerance: compaction.

Habitat:Alluvial flats; mesic ravines, moistEcosystemIntermediate wildlife value for

forest slopes. Services: waterfowl, songbirds, upland ground

birds, small mammals.

Hydrology: Intermediate tolerance of flooding;

moderate to well drainage; moist to dry.

Horticultural Golden yellow fall color. Compatibility:

Value:

Salt Moderately tolerant

Tolerance: Other: Susceptible to diseases: Dutch elm

Shade Tolerant of partial shade disease, cankers, Verticillium wilt;
Tolerance: disease, cankers, Verticillium wilt;
frequently susceptible to gypsy
moth, bark beetles, elm borer, etc.

Glossary

Acidic Pertaining to habitat or substances having a pH less than 7

Alkaline Pertaining to habitat or substances having a pH greater than 7

Allelopathic Related to the release by a plant of chemicals which suppress the

growth of nearby competing plants

Anaerobic An environment without oxygen; commonly occurring in water

saturated soils

Annual A plant which has a life cycle completed in a single year or

growing season

Aromatic Having a noticeable and pleasant smell; fragrant

Biennial A plant which has a life cycle completed in two years, where

blooming occurs in the second year

Biodiversity The existence of many different kinds of plants and animals in an

environment

Canopy The highest layer of branches in a forest or on a tree. A protective

covering

Canopy Cover The proportion of land area covered by tree crowns, as viewed

from the air

Catkin A dense spike or raceme bearing many small flowers or fruits

Colonial Of or relating to a colony; owning or made up of colonies

Columnar Having the shape of a column

Conical Having the shape of a cone

Coniferous A plant which bears its seeds in cones

Culm The stem of a grass or a sedge

Deciduous Having a life cycle in which foliage is shed and regrown annually

Dioecious Individual plants are of a single sex; Plants of both sexes must be

present on the same site or nearby for reproduction to occur

Drought A period of below average rainfall, longer than a dry spell

Ecosystem A system in which plants and animals interact with one another

and their physical environment

Ecosystems Services The benefits that people obtain from an ecosystem; there are four

types: provisioning, regulating, cultural, and supporting

Ephemeral A plant which completes its life cycle in a short period of time,

often just a few weeks

Evergreen Remaining green throughout the winter

Fauna Animals, considered as a group

Fern Flowerless, seedless plant that reproduces by spores

Floodplain An area of low, flat land along a stream or river that may flood; An

area of land built up from soil left by floods

Flora Plants, considered as a group

Forb A herbaceous flowering plant other than a grass

Forest A relatively large area of mature trees

Forever Wild Highest quality natural areas owned by NYC Parks

Fragmentation Breaking up of one patch of habitat into several smaller patches;

Isolation of one habitat fragment from other areas of habitat

Frond The leaf of a fern

Globular Having the shape of a globe

Graminoid Any of the grass-like plants, including grasses, sedges, and

rushes

Grassland Land covered with grasses and other soft plants but not with

bushes and trees

Groundwater Water within the earth especially that supplies wells and springs

Hardwood The wood of a tree, such as an oak or maple, that is heavy and

hard

Herbaceous Flowering plants which do not have woody stems, and which die

back to the ground, wholly or in part, at the end of the growing

season

Hydrology A science dealing with the properties, distribution, and circulation

of water on and below the earth's surface and in the atmosphere

Indigenous Produced, living, or existing naturally in a particular region or

environment

Inflorescence The arrangement of flowers on a stem

Invasive Species A non-native species whose introduction does or is likely to cause

economic or environmental harm or harm to human health

Landfill A system or area in which waste materials are buried under the

ground

Larvae The juvenile stage of many insect species, resembling a caterpillar

Loam A type of soil that is good for growing plants. A mixture composed

chiefly of moistened clay

Maritime Located near or next to the sea

Marsh An area of soft, wet land that has many grasses and other plants. Mineral Soil

Soil derived from minerals or rocks and containing little humus or

organic matter

Non-native Species A species introduced outside its natural past or present

distribution

Overstory The layer of foliage in a forest canopy; the trees contributing to an

overstorv

Ovoid Having the shape of an oval

Perennial A plant which has a life cycle which occurs over several years.

and using the same rootstock to produce growth

Permeability The quality or state of being permeable

Plant Community A collection or association of plant species within a designated

> geographical unit, which forms a relatively uniform patch. distinguishable from neighboring patches of different vegetation

types

Raceme An unbranched flower cluster in which individual flowers are

distributed at intervals along a central stalk

A horizontal underground stem of some plants, which sends out Rhizome

roots and shoots from its nodes

Rosette A cluster or leaves in crowded circles or spirals arising basally

from a crown or apically from an axis with greatly shortened

internodes

Runoff Water from rain or snow that flows over the surface of the ground

into streams

Salt Tolerance The degree to which a plant can withstand moderate or high

concentrations of salt

Samara The winged fruit of trees such as ash, elm, and maple

Sandy Loam A loam consisting of less than 7 percent clay, less than 50 percent

silt, and between 43 and 50 percent sand

Saturated Soil Soil in which all easily drained pores between soil particles are

temporarily or permanently filled with water

Savanna A grassland with occasional trees

Shade Tolerance The ability of a plant to tolerate shade

Shrubland Land on which shrubs are the dominant vegetation

Softwood The wood of a tree that is soft and easy to cut

Soil Compaction The process by which stress is applied to a soil causing

densification as air is displaced from the pores between the soil

grains

Species A group of animals or plants that are similar and can produce

young animals or plants: a group of related animals or plants that

is smaller than a genus

Stamen The structure in a flower which produces pollen.

Stipe The stalk of the front of a fern

Stormwater Water that is not absorbed into soil and rapidly flows downstream,

increasing the level of waterways

Strobiles Scaly multiple fruits resulting from the ripening of an ament in

certain plants, such as the hop or pine; a cone

Succession Unidirectional change in the composition of an ecosystem as the

available competing organisms and especially the plants respond

to and modify the environment

Tidal Of, relating to, caused by, or having tides; periodically rising and

falling or flowing and ebbing

Understory An underlying layer of vegetation; the vegetative layer, between

the forest canopy and the ground cover

Upland Ground elevated above the lowlands along rivers or between hills

Vegetative Spread The propagation of plants by nonsexual processes or methods

Well Drained Water is allowed to percolate through reasonably quickly and not

pool

Wetland An area of land that is covered often intermittently with shallow

water or have soil saturated with moisture

Woodland A circumscribed area of vegetation dominated by a more or less

closed stand of short trees
